## Appendix I

#### **Occupant Comfort & Satisfaction Survey**

Questionnaire: As employees working in a LEED certified building your experiences and opinions are valuable. The following questionnaire is intended to aid in the examination of the performance of LEED certified buildings within Thailand. Current environmental concerns, such as climate change, deforestation and biodiversity loss have indicated that we must find environmentally friendly alternatives. By examining the performance of green buildings we can determine if they are living up to their predicted performance standards. As employees who work in a certified building your participation is crucial and is greatly appreciated.

#### Appendix IV

#### **EKC Methodology**

#### RESEARCH DESIGN

The EKC analysis defines GDP as the independent variable with SO<sub>2</sub>, NO<sub>2</sub>, PM<sub>10</sub> and CO as the dependant variables. A descriptive research approach was used. Although key variables have been established, the causality of this relationship has only been theorized and not definitively tested. A longitudinal design has been designated as the EKC analysis is a trend study in order to establish the trend between the independent and dependant variables. The EKC analysis uses quantitative research derived from secondary data and has been modeled after preceding studies.

#### RESEARCH POPULATION & SAMPLE

The population consists of all elements that are included in the government database, which have documented historical key air quality metrics. A criterion sample was used as only facilities which met the criteria were utilized.

#### RESEARCH METHOD

The EKC analysis uses a quantitative method in which secondary data was gathered through a government database. The EKC is analyzed in order to establish a correlated trend between air quality and GDP. The Thai Meteorological Department, Bangna and the Thonburi Power Substation were utilized as they provided the most complete data sets spanning from 1996 to 2010. Although many facilities have kept records of air quality metrics in recent years, very few kept records dating back to 1996 in which the earliest set of records are available within Thailand. Both facilities were chosen due to their ability to provide the most complete data sets. Additionally, using data sets from single, consistent sources minimizes inconsistencies in variables and measurement techniques.

#### DATA COLLECTION

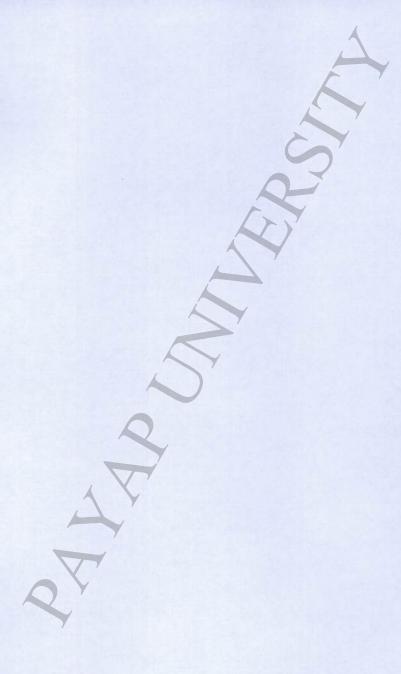

The EKC analysis utilized secondary data obtained through formal letters of request. Air quality metrics were provided by the Pollution Control Department: Air Quality and Noise Management Bureau's database, and was supplied as raw data from the Thai Meteorological Department, Bangna and the Thonburi Power Substation's historical, monthly records.

#### DATA CRITERIA

Participating facilities must be part of the air quality database provided by the Pollution Control Department: Air Quality and Noise Management Bureau. Further, they must provide consistent data sets spanning from 1996 to 2010.

### **DATA ANALYSIS**

The EKC analysis was designed as a trend study. Quantitative data was used in a quantitative analysis of raw secondary data. Secondary data was taken in monthly measurements and then combined to form a yearly average from 1996 to 2010.A trend analysis of the independent and dependent variables was used to compare GDP to key air quality metrics including SO<sub>2</sub>, NO<sub>2</sub>, CO and PM<sub>10</sub>.

## Appendix V

## Methodology (method of Estimation)

#### METHOD OF ESTIMATION TERMOLOGY

Modeled baseline- is a performance estimate of the energy and water consumption for a similar building that does not include green features consistent with ASHRAE 90.1. This figure is generated by the project team and used during the certification process.

Predicted estimate- is performance estimate of energy and water consumption of the designed building. In this case, ISB's Cultural Center's predicted consumption. The predicted estimate was generated by the project team and was used by the project team.

Actual measured- is the actual measured performance generated from billed energy and water consumption. In this case, it is the billed energy and water consumption of ISB's Cultural Center.

National average EUI- is the national average energy use intensity of Thailand's non-certified buildings given in a yearly average.

Sector-based EUI- is the national average energy use intensity of Thailand's non-certified buildings by sector. In this case average EUI of educational facilities given in a yearly average.

Actual measured EUI- is ISB's yearly average EUI generated using actual measured performance.

#### METHOD OF ESTIMATION

Energy consumption: Data is measured energy use of the whole building included in monthly energy bills. Site energy use was chosen over source energy use, as it is the most useful metric to owners. Site energy is the more easily controlled by owners and therefore deemed the most useful. Furthermore, site energy is the basis for calculating source energy and is the most closely related to utility bill information. Energy consumption data will be used to report emission levels. Data will be provided for the most recent months available. Energy consumption data is further defined as:

Purchased Energy Only: Consistent with ASHRAE 90.1 and energy star, which excludes onsite renewables and is indicated by kilowatt-hours used including meter dates.

Annualized energy: This study requires a minimum of one year of energy consumption data to evaluate performance, however there is no maximum number of months specified and participants were encouraged to provide the longest post-occupancy data set possible. Longer data sets show long-term performance and minimize sporadic changes attributable to short-term problems.

Water consumption: Data was includes meter start/end dates and billed on-site usage.

Financial analysis: Actual measured energy and water consumption was compared to both the modeled baseline and the predicted estimate, i.e., actual energy/water consumption vs. modeled baseline energy/water consumption and actual measured energy/water consumption vs. predicted estimate energy/water consumption. In order to compare actual performance to average, non-certified performance and actual performance to expected performance. Energy consumption is then converted into energy costs using the Metropolitan Electrical Authority's pricing structure for the greater Bangkok area while the cost of water was calculated using the Metropolitan Waterworks Authority's pricing structure. Actual measured costs were then compared to the estimated baseline model costs and the predicted estimate costs.

Environmental analysis: The environmental performance analysis is calculated in the same manner using the site energy consumption to estimate emissions. CO<sub>2</sub> emissions are then estimated for the actual measured, modeled baseline and the predicted estimate using:

ISB's actual measured, estimated emissions are then compared to the modeled baseline and the predicted estimate.

Energy Use Intensity (EUI): Is the most basic performance benchmark and represents both the financial and environmental performance of ISB's Cultural

Center. It is used in comparison with national average EUI and average EUI of buildings within the same sector and of a similar end use. This allows a comparison of the actual measured EUI to the national average and sector-based EUI.

EUI is calculated as follows:

EUI= <u>kWh/sf</u> n kWh= Kilowatt hours

sf= square feet

n= period of time
